

Capture anything, instantly.

A self-contained, serverless Android media engine.

Open Source • MIT License • 1000+ Sites Supported

The downloader landscape is fundamentally broken.

Ad-Infested Web Services

Web-based downloaders are plagued by malicious ads, aggressive popups, and services that mysteriously disappear overnight.

Shady Free Apps

Existing native apps act as trojan horses, demanding unnecessary access to your contacts, call logs, and precise location.

Insecure Thin Clients

Cloud-dependent apps send your private URLs and media requests to third-party servers, compromising your browsing privacy.

The server is entirely in your pocket.

ReClip packages a complete, heavy-duty extraction engine directly inside the APK. Your URLs never leave your device. Your downloads stay private. It works reliably, independent of third-party server outages.

0 External Conversion Servers

1000+ Supported Platforms

100% On-Device Processing

Local processing is the ultimate luxury.

Features	Web Services	Shady Apps	Thin Clients	ReClip
100% On-Device Processing	✗	✗	✗	✓
Zero Server Dependency	✗	✓	✗	✓
Ad-Free Experience	✗	✗	✓	✓

The Aurora Experience.

Audio Extraction

Native extraction to MP3 at 192 kbps via bundled libmp3lame, complete with embedded metadata and artwork.

Share-to-Download

Native Android intent support. Share a link from any app directly to ReClip for auto-fetching.

MediaStore Integration

Files appear instantly in your gallery and file manager at Downloads/ReClip.

Foreground Persistence

Background services keep your active downloads alive even when you switch applications.

Heavy machinery, lightweight footprint.

The Face — WebView UI

Pure HTML5, CSS3 backdrop-filters, and Vanilla JS. Zero frameworks.

The Translator — Java Bridge

Android WebView with @JavascriptInterface dispatching to background threads.

The Brain — Python Engine

Embedded Python 3.11 interpreter running yt-dlp via Chaquopy 15.0.1.

The Muscle — Native Media Layer

Statically cross-compiled FFmpeg 7.1 binaries with LAME, running via Android NDK r27c.

The anatomy of a local download.

User Input

URL pasted; WebView calls `ReClip.fetchInfo(url)` via JS interface.

Dispatch

Java bridge intercepts and dispatches the call to a background worker thread.

Metadata Extraction

Embedded Python runs `yt_dlp.YoutubeDL().extract_info()` via Chaquopy.

FFmpeg

Media Fetch & Muxing

Python streams the data and invokes the bundled FFmpeg library from a writable location.

Native Save

Java bridge utilizes Android MediaStore API to safely write the finalized file to `/Downloads/ReClip/`.

Power is the prerequisite for privacy.

Bundling a full Python 3.11 interpreter and cross-compiled FFmpeg results in a dense ~180MB application payload.

Because the engine is fully self-contained, ReClip requires zero location, contacts, or account permissions. It requests only standard network and storage access.

The architecture is what enables the privacy; the privacy is what enables the clean user interface.

The Open Horizon.

☐ Settings Screen
(Quality presets, naming patterns)

☐ Download Queue
(Parallel downloads, pause/resume)

☐ Playlist Support
(Full batch fetching)

☐ F-Droid Native Release

Fork the Android branch.

ReClip is open-source under the MIT License. We are actively seeking PRs for Android 14+ device testing, APK size optimization, and ARM v7 build support.

Build the engine locally with Android Studio Hedgehog+. First build packages Python — the wait is worth it.
